PLasma And Supra-Thermal  
Ion Composition investigation

## STEREO SWG: PLASTIC Science Snipits

Toni Galvin (UNH)  
for the PLASTIC Team

Special thanks to K. Simunac, B. Klecker

**STEREO PLASTIC Institutions:**  
**UNH, U Bern, MPE, U Kiel, NASA/GSFC**  
**IDPU/LVC provided by UCB (IMPACT)**

# PLASMA AND SUPRATHERMAL ION COMPOSITION INSTRUMENT

- **Solar Wind Sector (SWS) Small (Proton) Channel** measures the distribution functions of **solar wind protons ( $H^+$ )** and **alphas ( $He^{+2}$ )**, providing proton density ( $n$ ), speed ( $V_{sw}$ ), thermal speed ( $V_{th}$ ).
- **Solar Wind Sector (SWS) Main (Composition) Channel** measures the elemental composition, charge state distribution, and speed of the more abundant **solar wind heavy ions** (e.g., C, O, Mg, Si, and Fe).
- **Wide-Angle Partition (WAP)** measures distribution functions of **suprathermal ions**, including interplanetary shock-accelerated (IPS) particles associated with CME-related SEP events, recurrent particle events associated with Co-rotating Interaction Regions (CIRs), and heliospheric pickup ions.

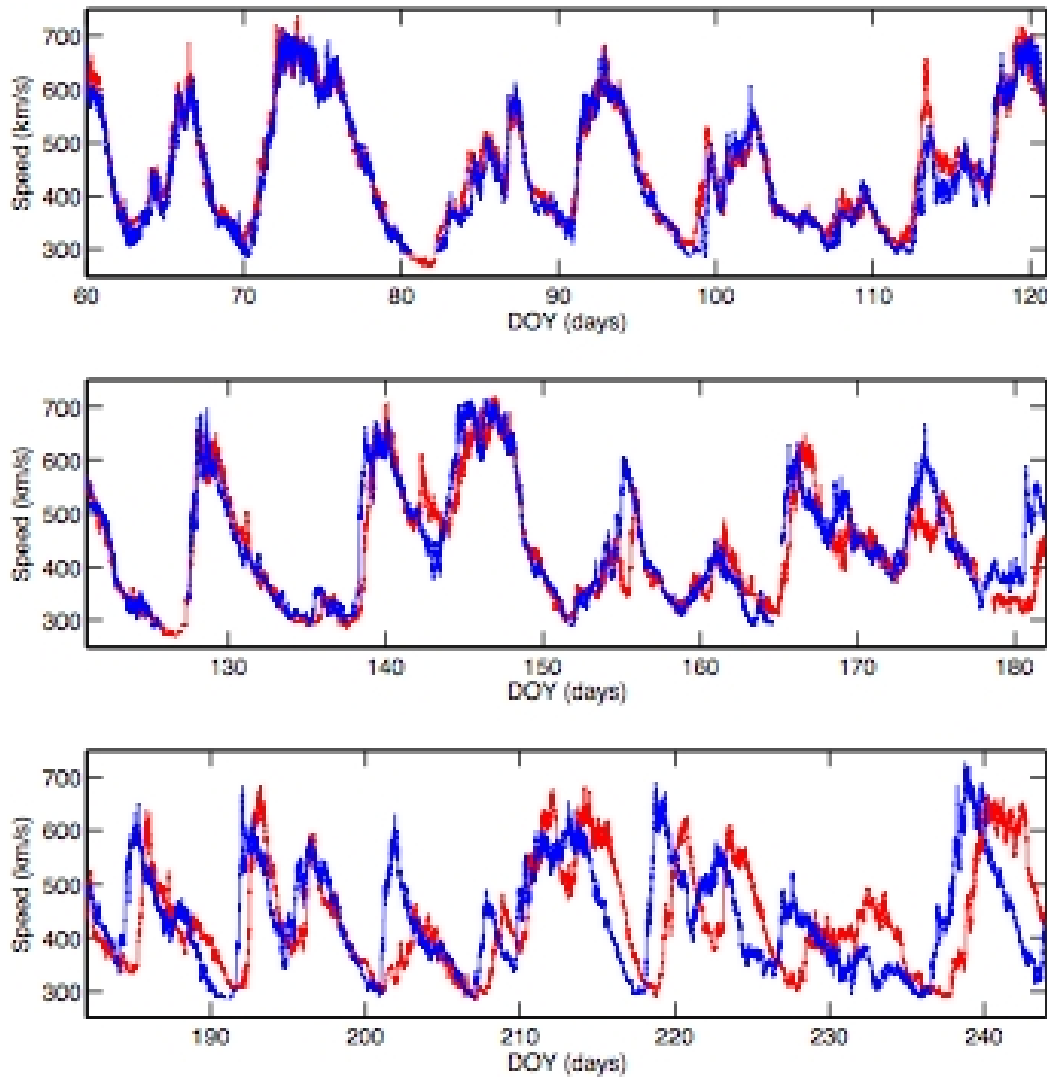

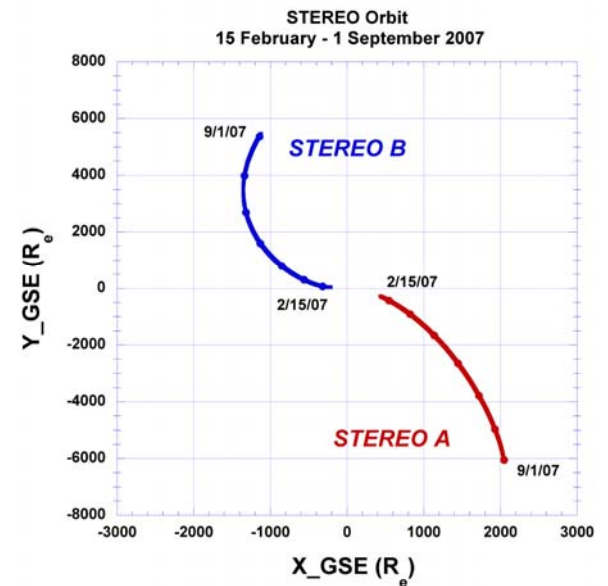

Figure 2 Solar wind speed measured by Stereo A (red) and Stereo B (blue) from 2007 March 1 (DOY 60) through 2007 August 31 (DOY 243).

Podesta et al 2007

## Work in Progress (PLASTIC)

- Solar wind and suprathermal processes and composition at (CIR) stream interfaces (PLASTIC, IMPACT/MAG; Galvin, Popecki, Barry, et al.)
- Variability of suprathermal He<sup>+</sup>, correlations with SOHO STOF (Klecker et al).
- Extended X-line reconnection (exhaust events) (IMPACT with PLASTIC, Gosling et al., Eriksson et al, with Simunac, Blush).
- Solar wind helium and minor ion velocity distributions (Karrer, Bochsler, Popecki, Walker et al)
- Bulk parameter determinations and multi-spacecraft comparisons of solar wind CIR structure and spatial geometry - STEREO, Wind, ACE, SOHO (Simunac et al.)
- Reconstruction of magnetic clouds using observations from two spacecraft (Farrugia, Möstl, Leitner et al.) Case Study: the May 22 2007 Flux Rope Event (study led by Huttunen, with contributions by Farrugia and Möstl: )
- Composition in the slow and fast solar wind (Daoudi, Popecki, Galvin, Karrer , et al.)
- Deep magnetotail observations by STEREO B - Energetic O<sup>+</sup> (PLASTIC with IMPACT/MAG and SWEA, Kistler et al.)
- Correlation lengths in the solar wind tangent to the earth's orbit (Podesta et al., Opitz et al.)

# Snip-it Outline

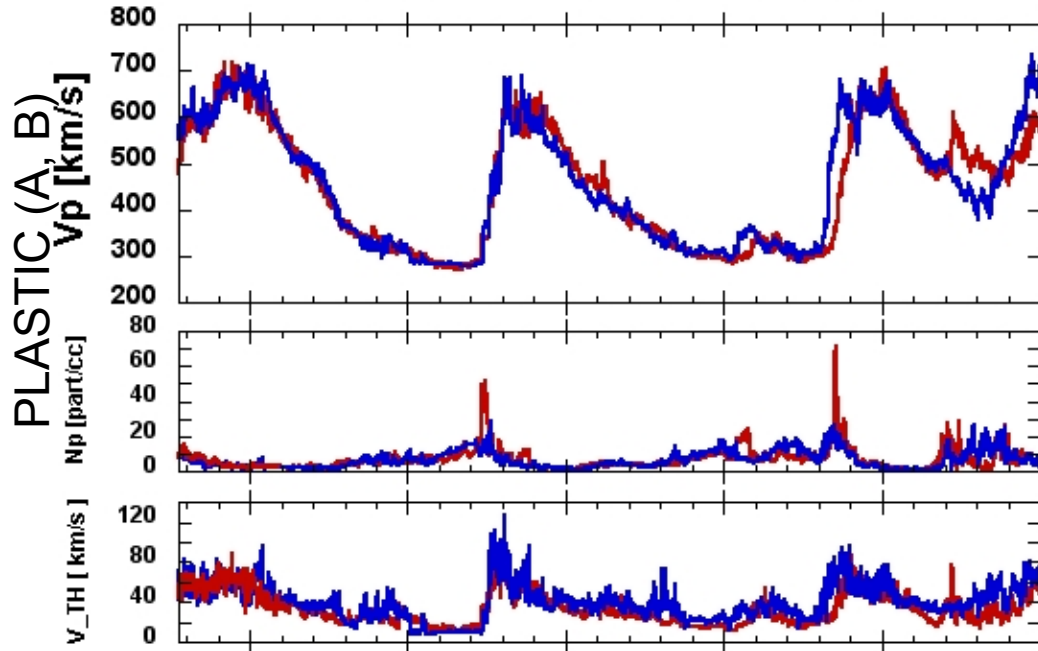

- Some science snip-its at CIRs
  - Geometry of the Structure (predicting or mapping back)
  - Compression region
  - Pickup ion energy distribution

# Fast Wind and Slow Wind Interact and Evolve into Corotating Interaction Regions

Pizzo, V. (1978), A three-dimensional model of corotating streams in the solar wind: 1. Theoretical foundations, J. Geophys. Res., 83, 5563–5572.

### Solar Wind Bulk Parameters CR 2056

High speed and low speed interaction regions:

Regions are seen in both solar wind proton and magnetic field bulk parameters.

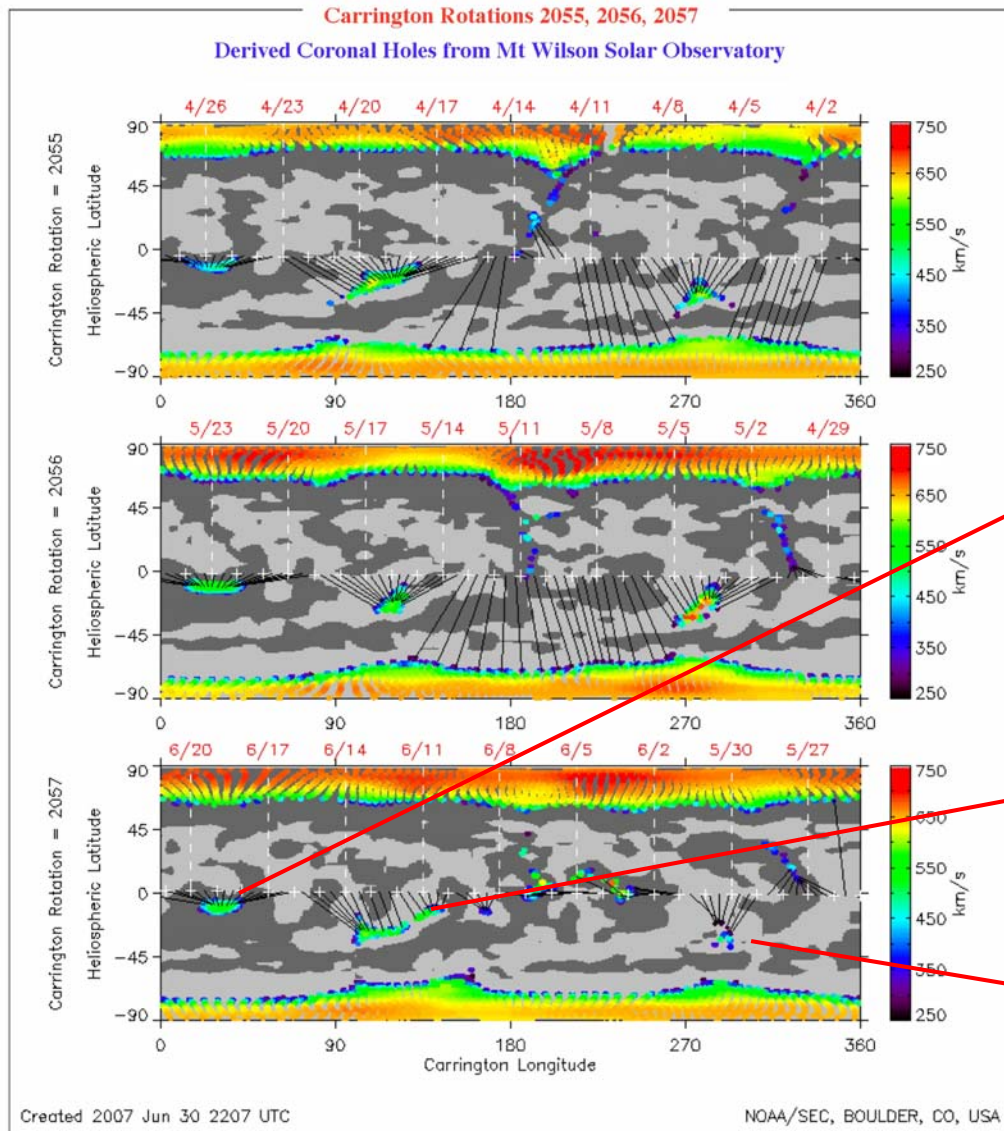

# STEREO Observations of the 2-D Geometry of Co-rotating Solar Wind Streams (Simunac et al.)

## Some Motivation

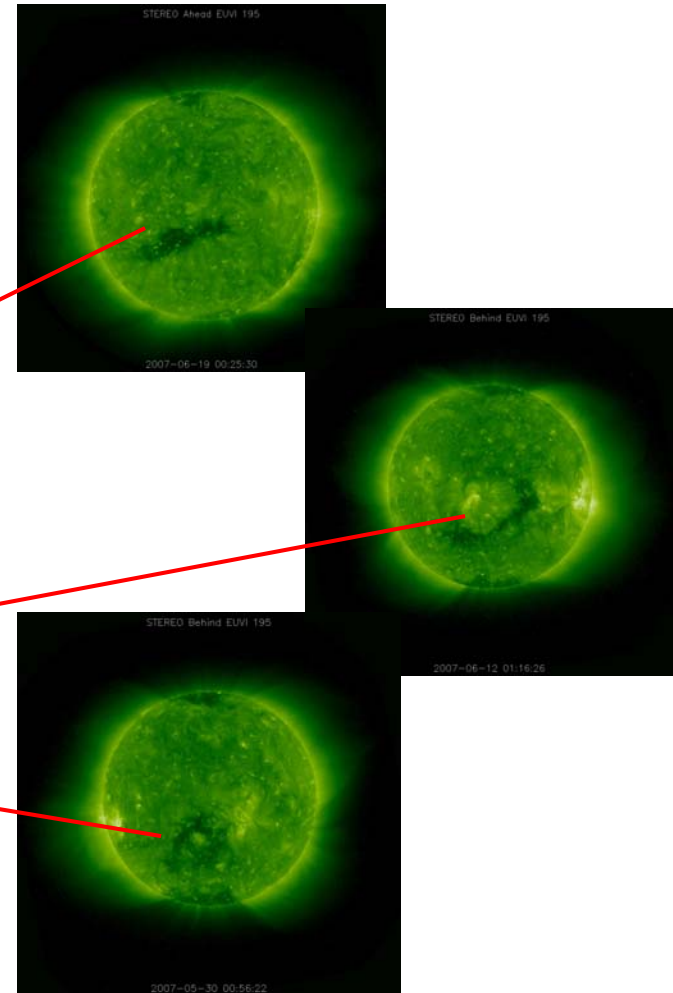

**Mapping large-scale solar wind structures back to the Sun:**

**Science: identification of coronal source region for correlation studies with in-situ**

**Application: prediction of arrival of CIR structure to Earth or other spacecraft using “early warning” from s/c located at other longitudes**

Solar sources for the high speed solar wind - long lived polar and equatorial coronal holes - observed by SECCHI EUVI (B).

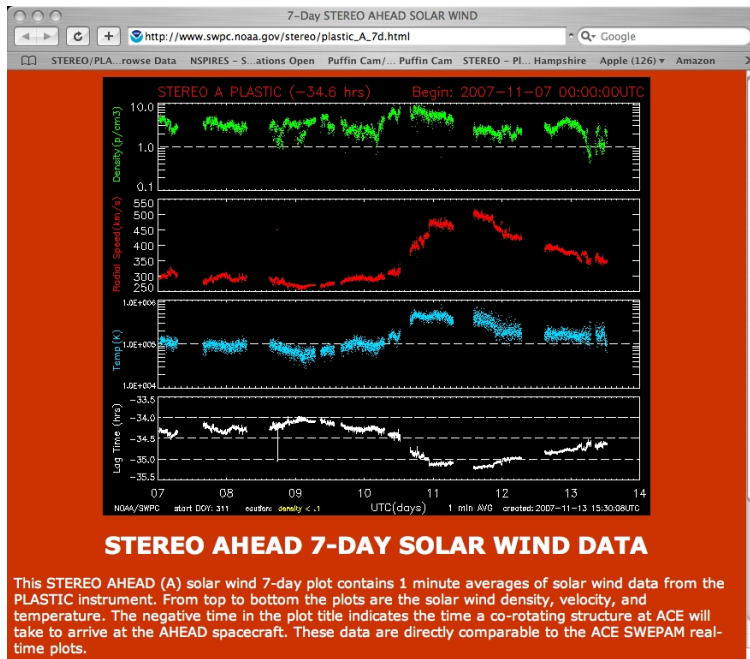

Science:

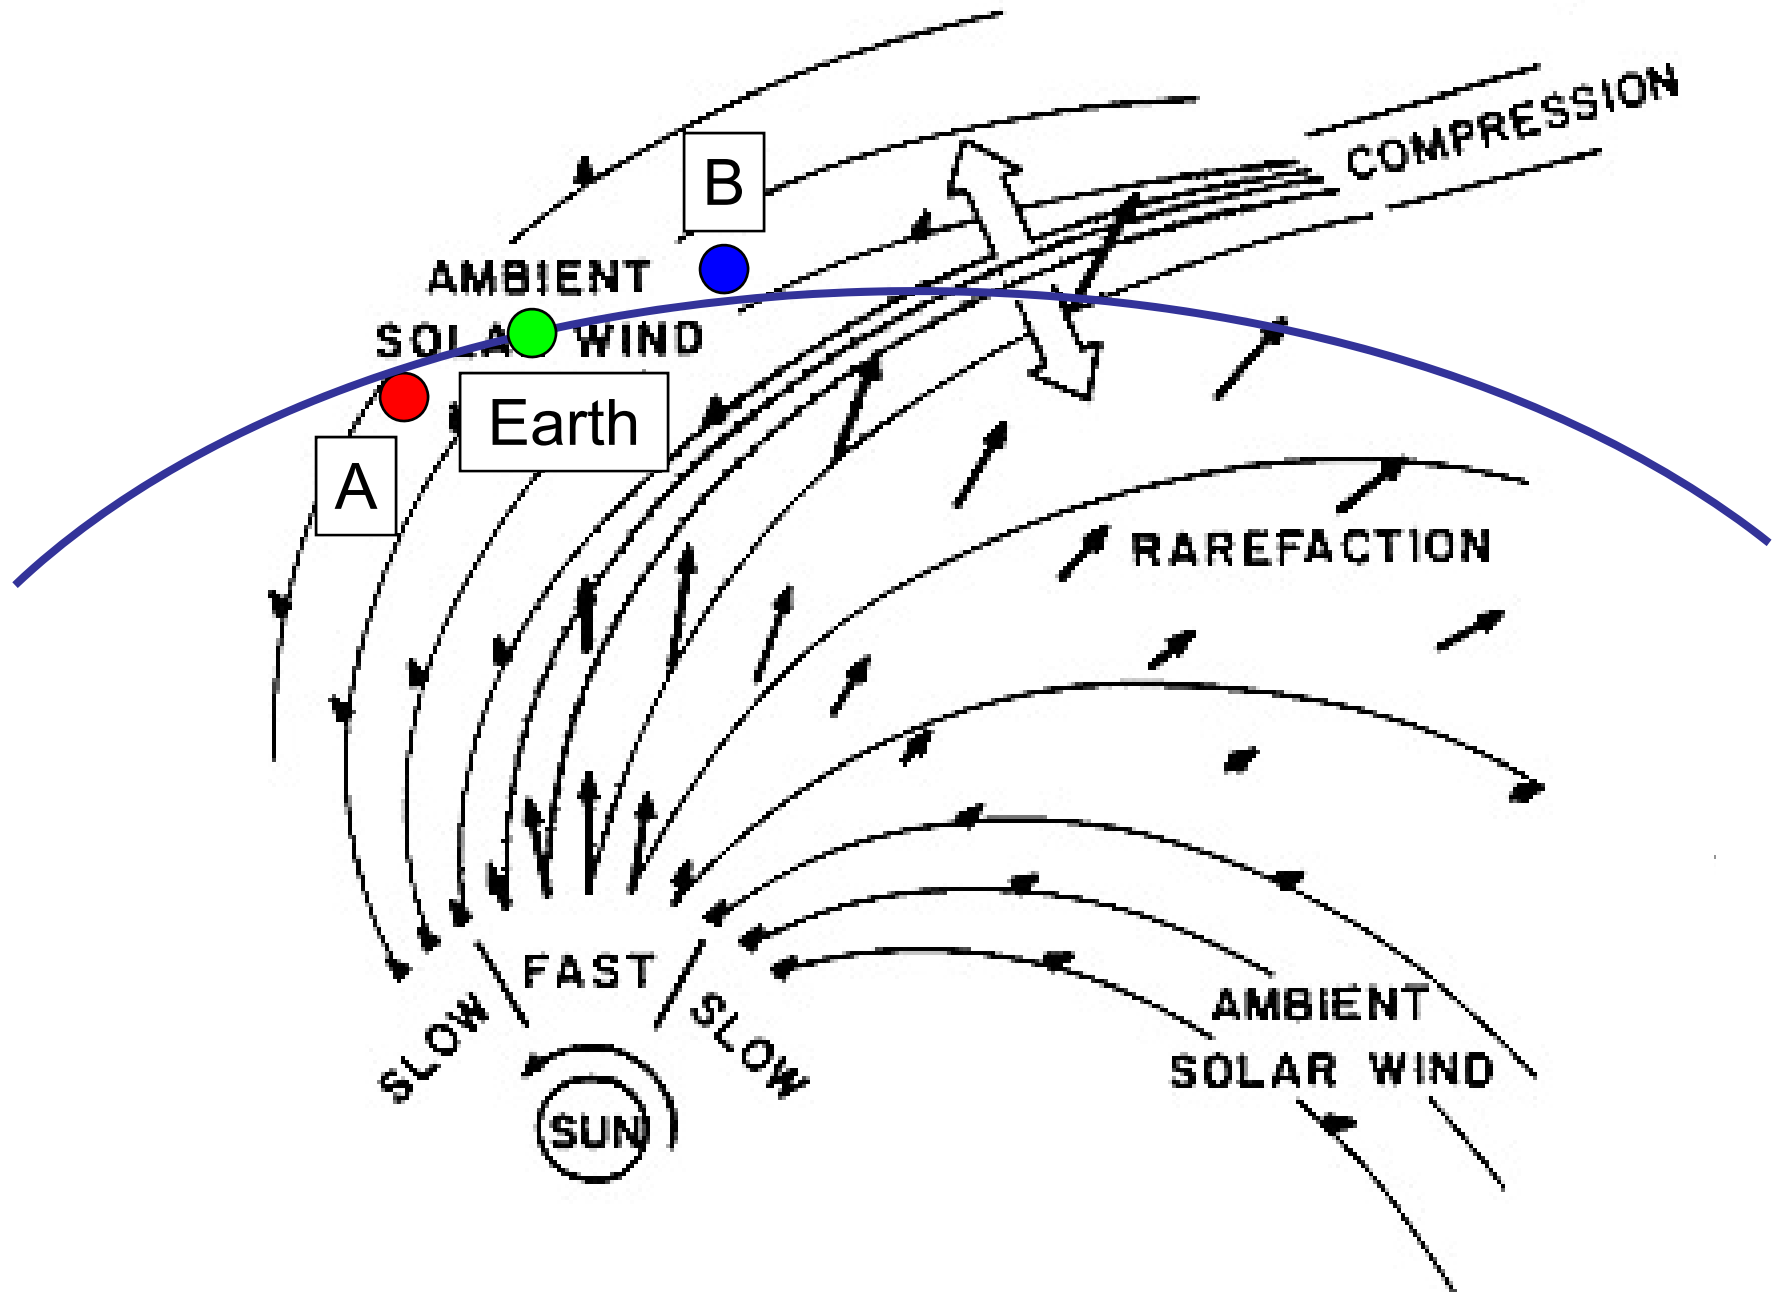

Fast: from CH    Slow: More than one source?

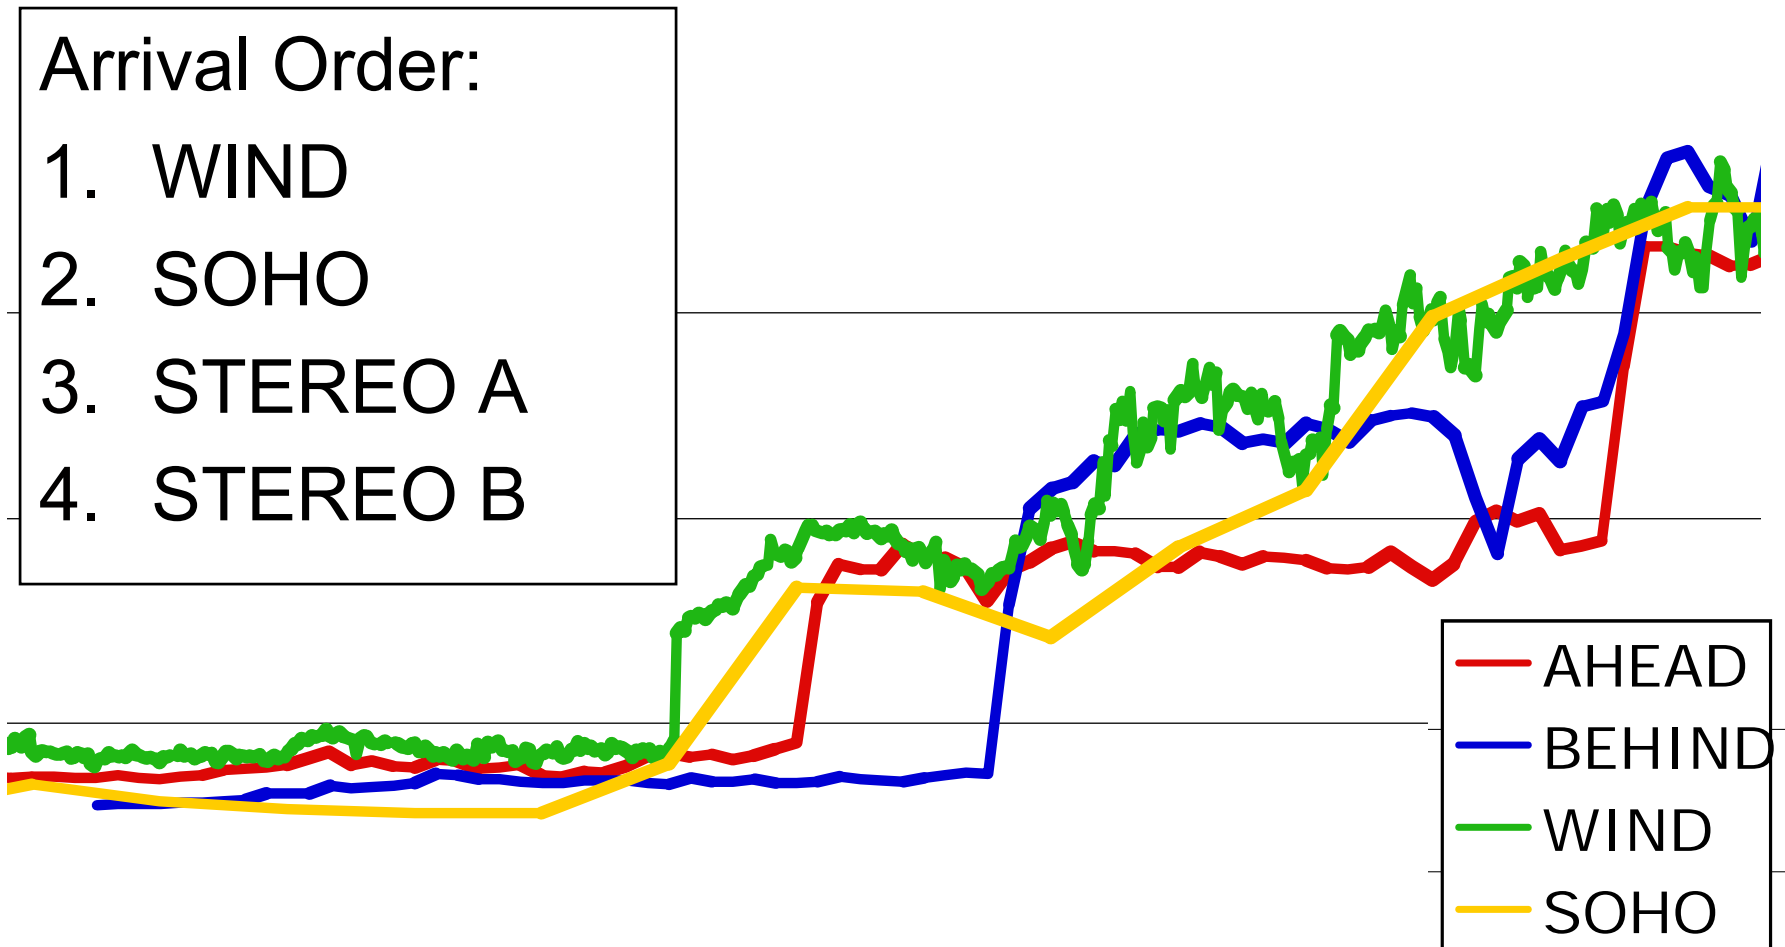

# Application (NOAA SEL)

- Using s/c at different solar longitudes to predict arrival of large scale structures at other locations (L1, Earth, ...)

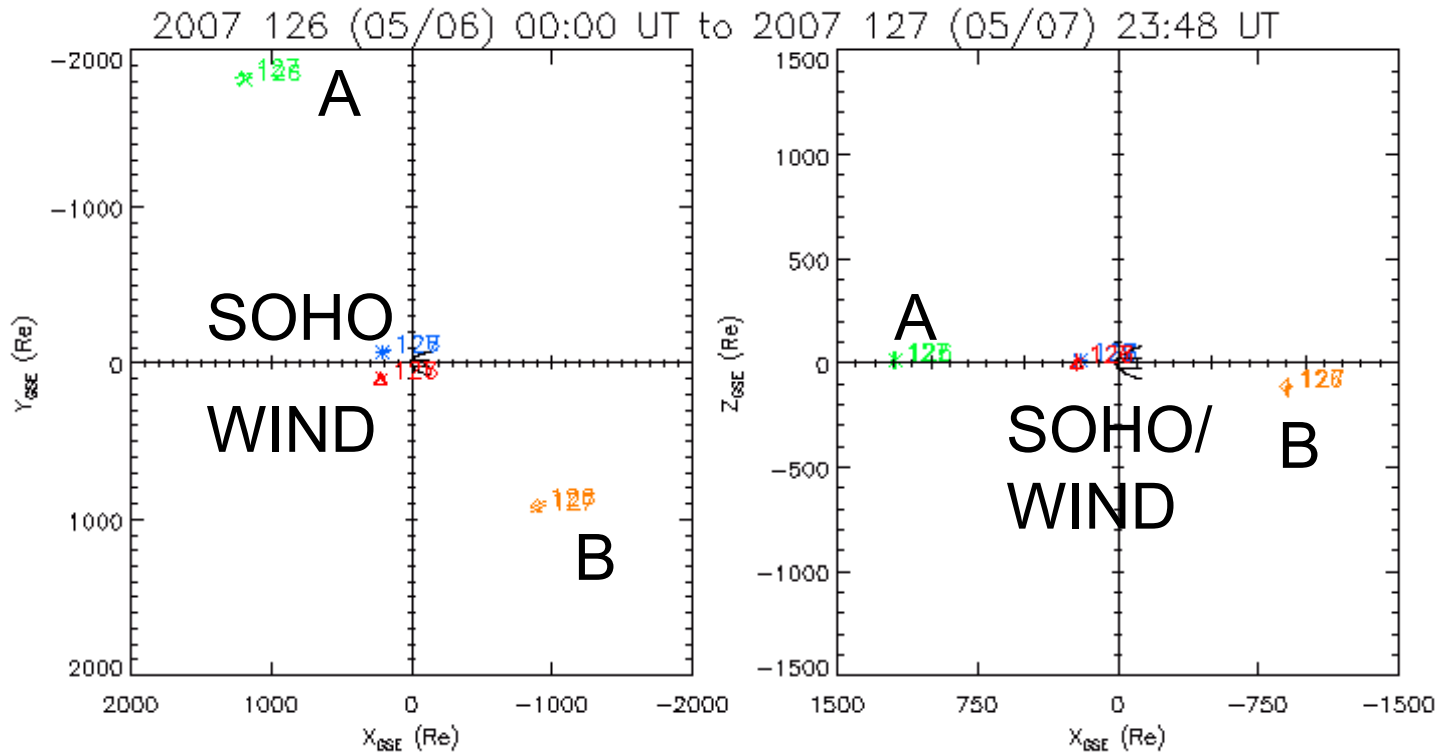

# Not always obvious: Note Arrival Order of CIR Forward Shock in the March 7, 2007 Event

# 7 May, 2007 spacecraft locations

In-Ecliptic

Out-of-Ecliptic

# 7 May, 2007 spacecraft locations

In-Ecliptic

Out-of-Ecliptic

# Sophisticated model predictions are available:

Model at CCMC: ENLIL

**Modeled solar  
wind for May 7  
2007 by CCMC  
using ENLIL code**

## ‘Back of envelope’ simple methods :

- The simplified constant velocity approximation is usually reasonably good for the CIR trailing edge
- For CIR leading edge, testing use of “traveling interface technique” (Schwenn, 1990). Structure takes shape of “Parker-type” spiral with curvature expressed from “effective propagation speed”.

# “Parker Spiral Angle”

$$\tan \alpha = \frac{\Omega_{sun} R}{V_{sw}}$$

$$\alpha = 45^\circ \text{ at } 1 \text{ AU when } V_{sw} = 400 \text{ km / s}$$

# Effective Propagation Speed

Schwenn (1990) defines an effective propagation speed based on two simultaneous observations of a stream interface.

$$v = \frac{\Omega_{sun} (R_1 - R_2)}{(\phi_1 - \phi_2)}$$

(This is simply based on the geometric definition of an Archimedes spiral.)

# Effective Propagation Speed

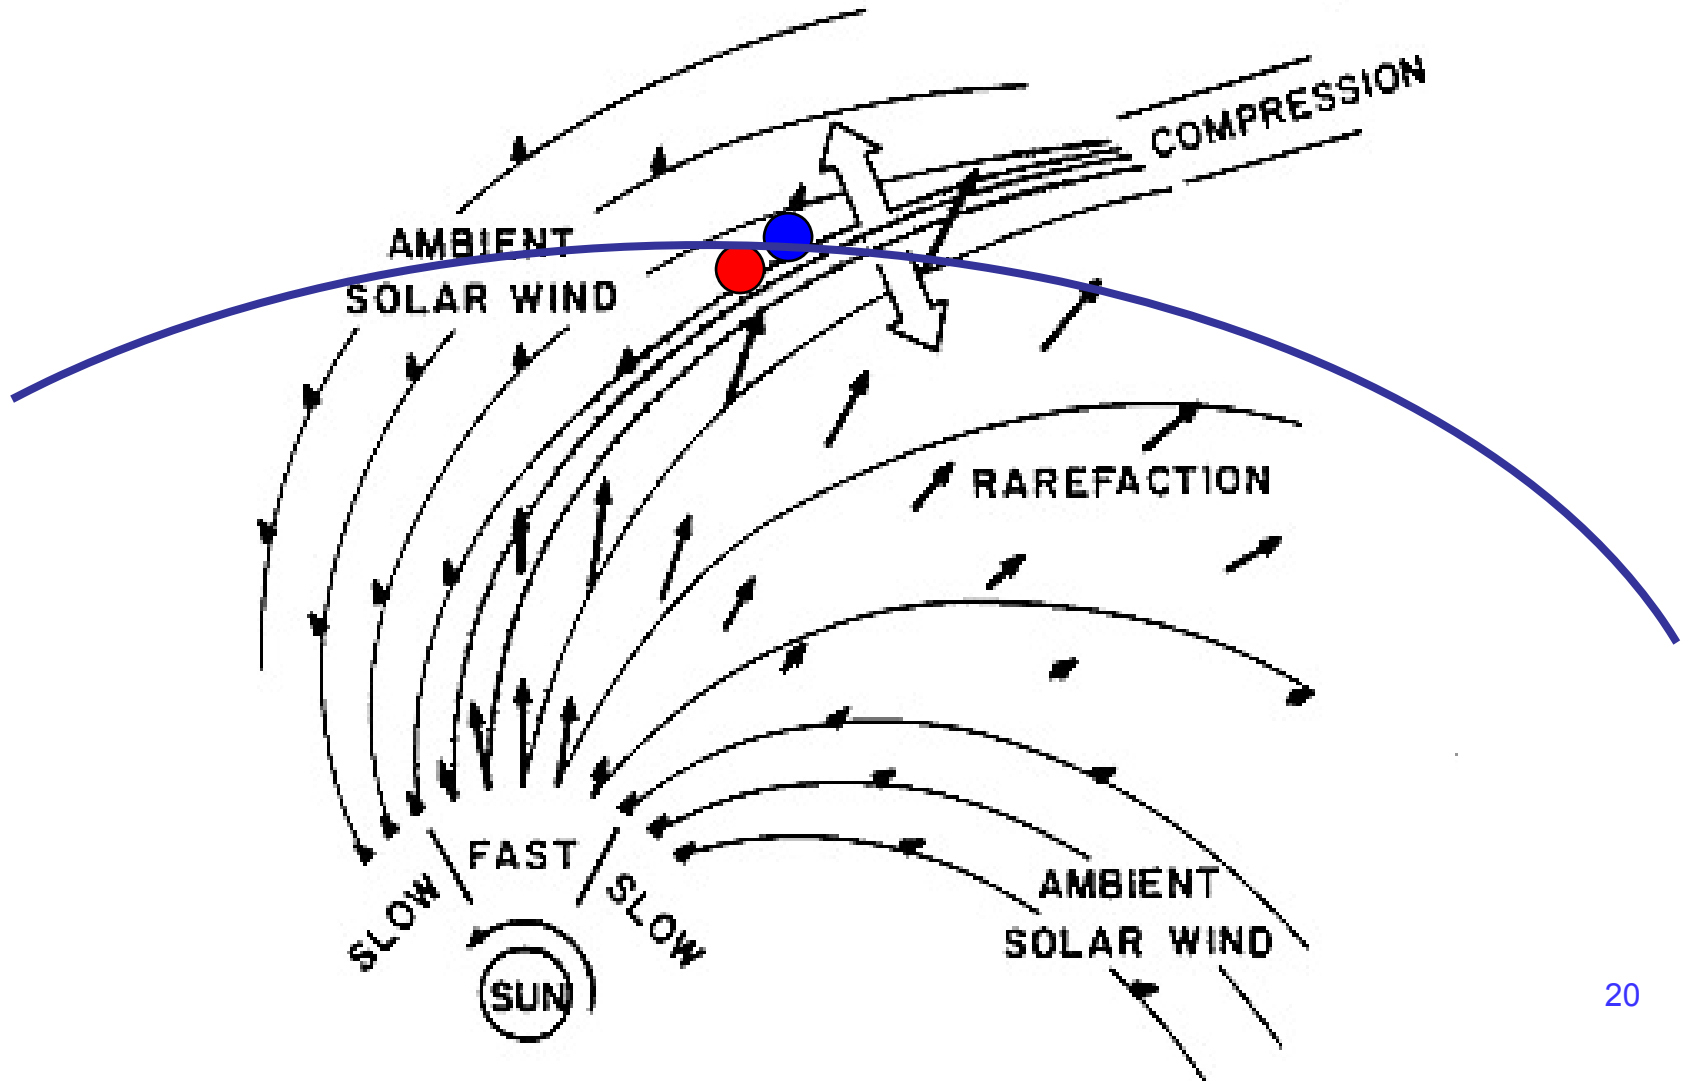

Adapting for non-simultaneous observations on A and B:

$$v = \frac{\Omega_{sun} (R_B - R_A)}{(\phi_A - \phi_B - \Omega_{sun} t)}$$

# Example Case Study

Radial and Longitudinal Separation are Similar

# 12 March, 2007

Separation  
Angle with  
Earth

A:  $1.444^\circ$   
B:  $0.312^\circ$

Angle  
between A  
and B:  
 $1.746^\circ$

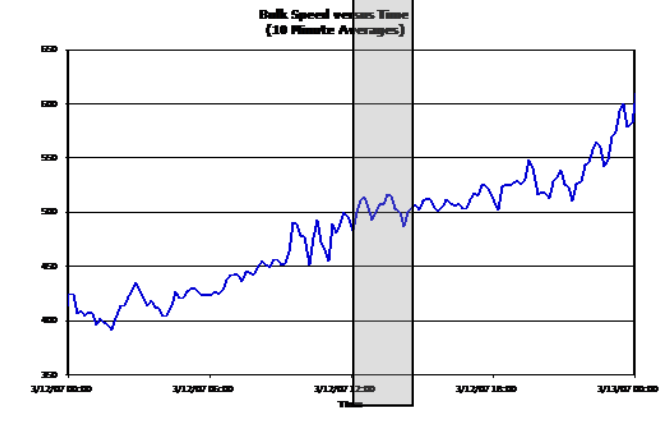

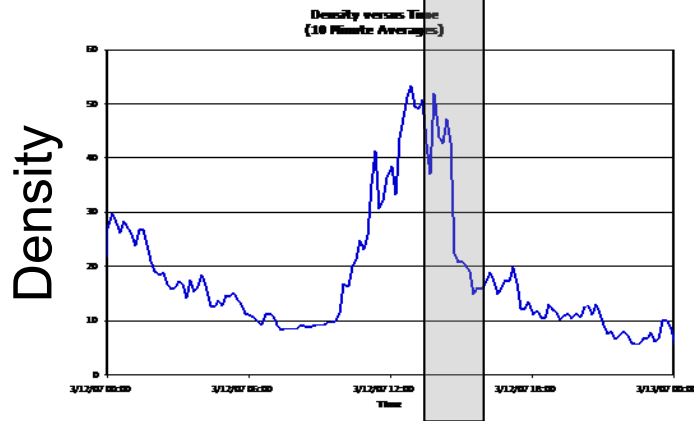

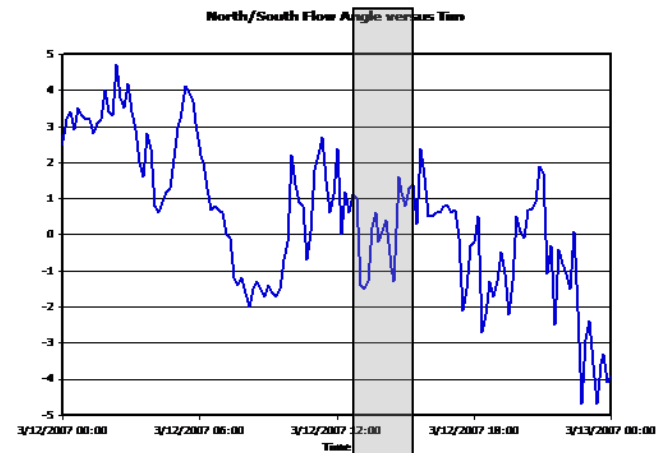

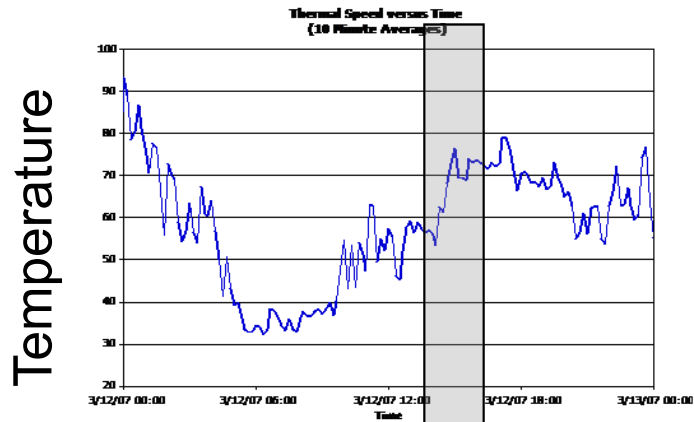

Distance  
from Sun  
(AU)

A: 0.967  
B: 1.010

Earth:  
0.994

# STEREO B: Stream Interface

14:40 UT 12 March, 2007

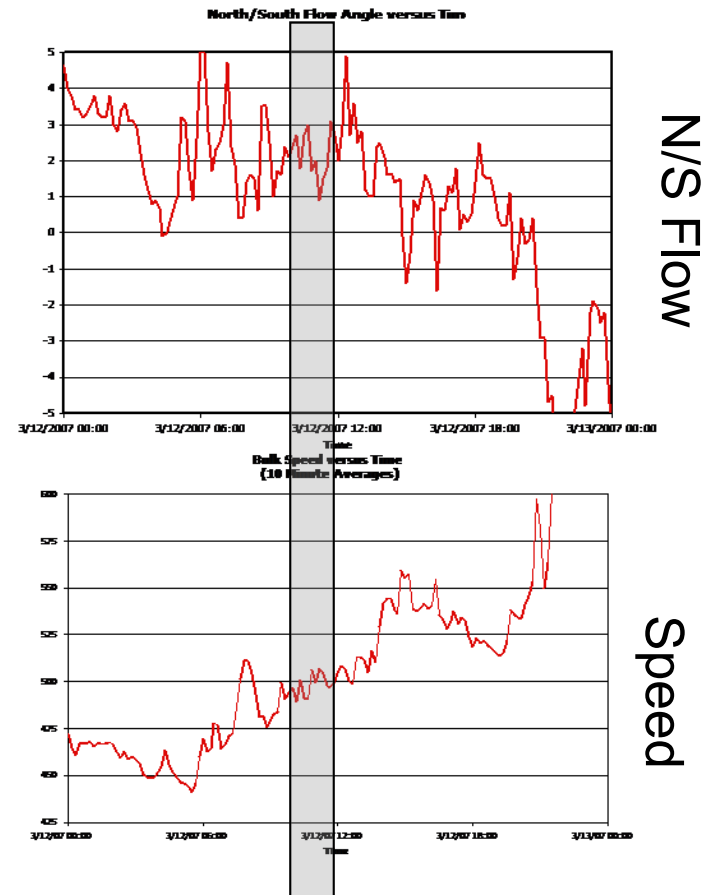

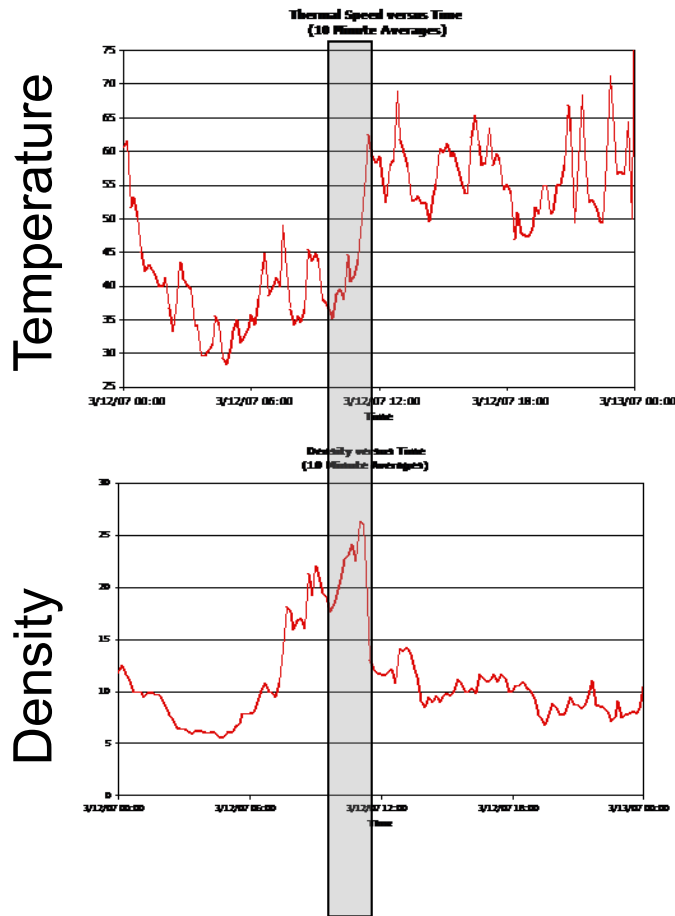

N/S FLOW

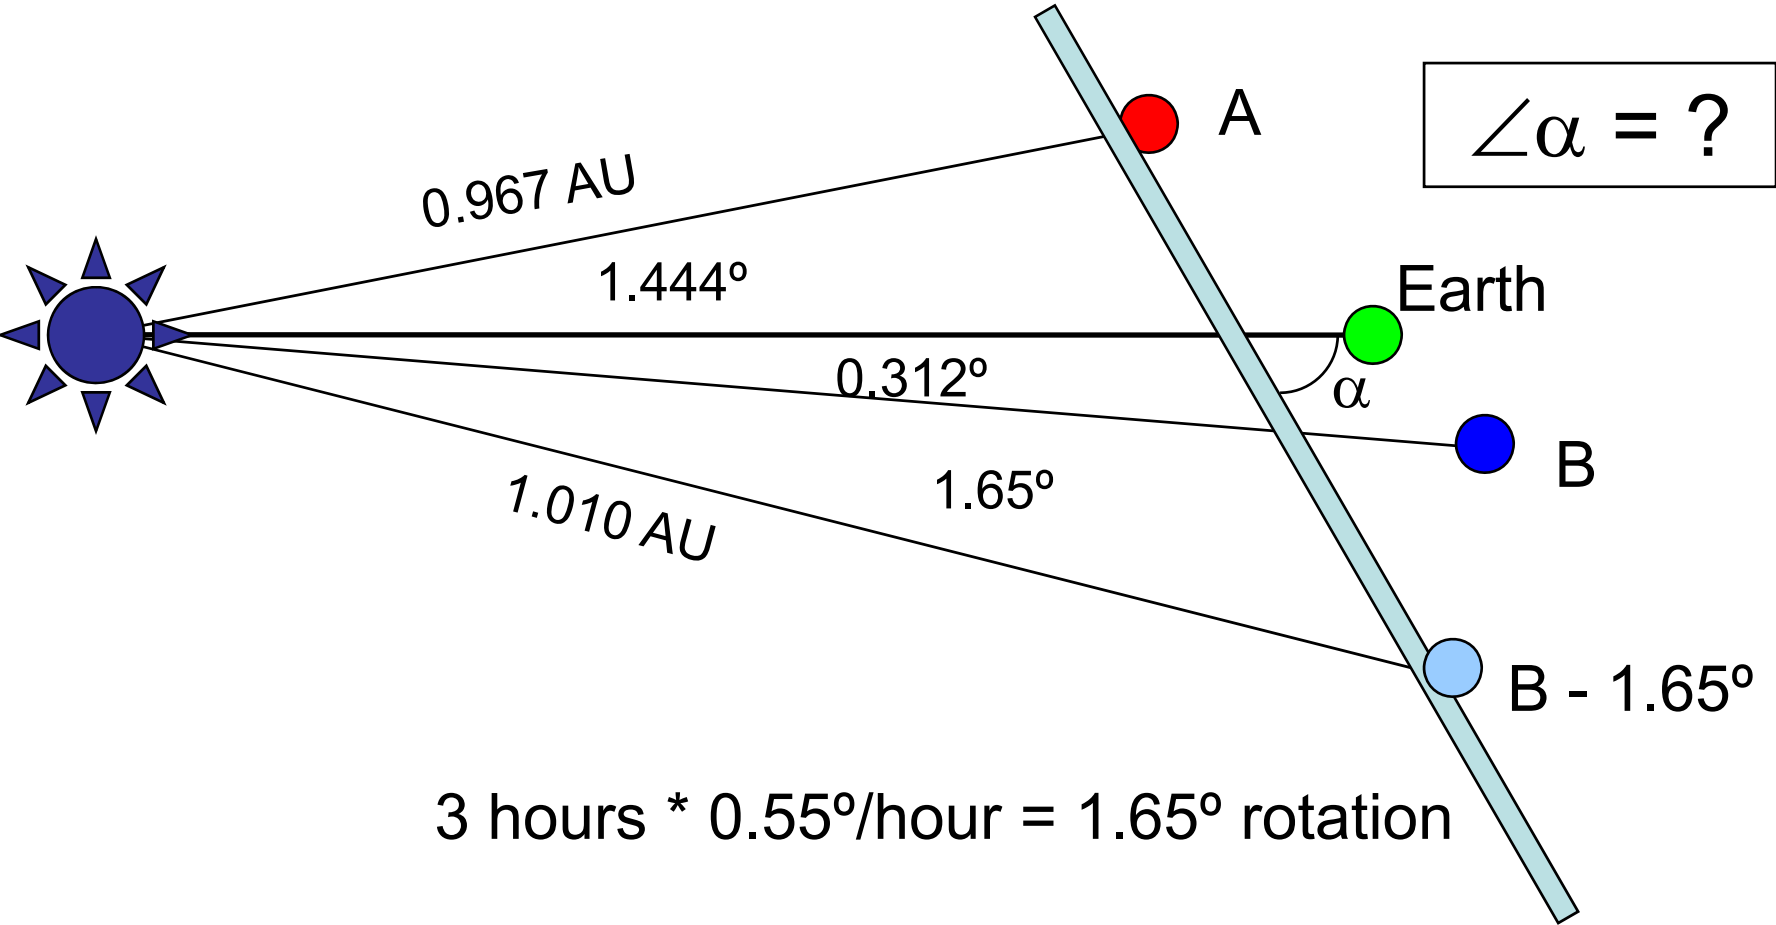

Speed

# STEREO A: Stream Interface

11:40 UT 12 March, 2007 (3 hour earlier than B)

# A Geometry Exercise

3 hours \* 0.55°/hour = 1.65° rotation

CARTOON IS NOT TO SCALE!

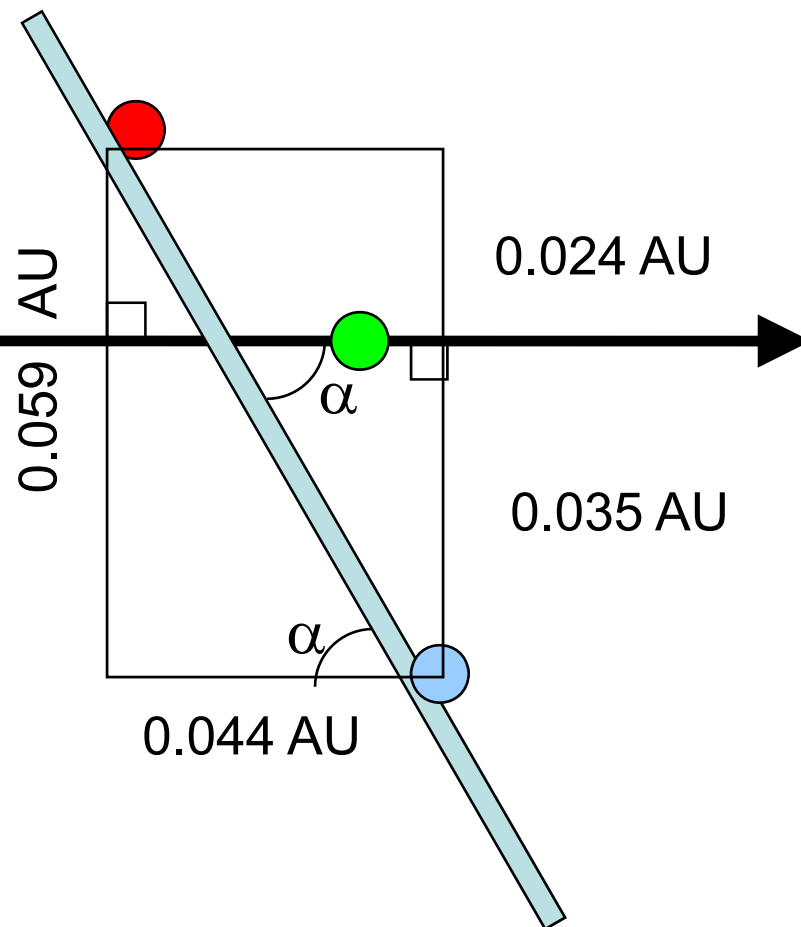

## Parallel Lines and Similar Triangles

$$\angle \alpha = 53^\circ$$
$$R = 0.984 \text{ AU}$$

How does this compare with the garden hose angle?

Expected  $\alpha =$   
 $\text{Arctan}(\Omega_{\text{sun}} R / V_{\text{sw}})$

# Solar Wind Speed

## Minimum Speed Prior to Interface

**Bulk Speed versus Time**

# Agreement

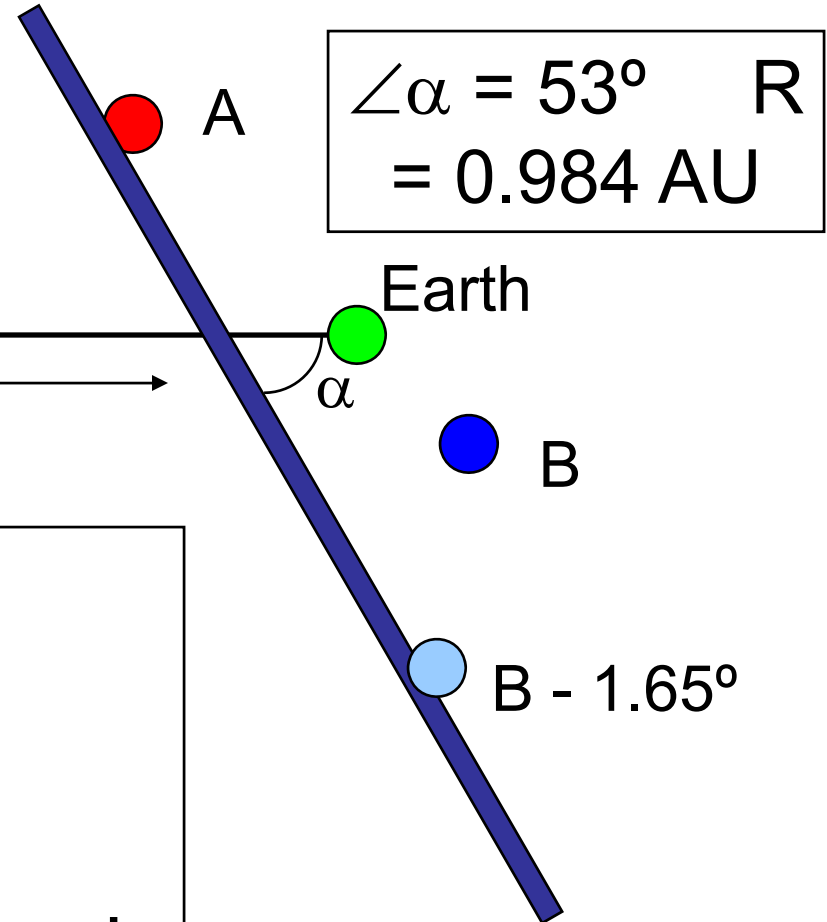

$$\Omega_{\text{sun}} = 2.67 \times 10^{-6} \text{ rad/s}$$

$$R = 0.984 * 1.496 \times 10^8 \text{ km}$$

$$V_{\text{sw}} = 300 \text{ km/s}$$

← 0.984 AU →

Expected  $\alpha = 52.6^\circ$

Good agreement with garden hose angle for minimum solar wind speed.

# Effective Propagation Speed

Inserting values into the propagation speed calculation:

$$v = \frac{\Omega_{sun} (R_B - R_A)}{(\phi_A - \phi_B - \Omega_{sun} t)}$$
$$v = \frac{(1.53 \times 10^{-4} \text{ } ^\circ / \text{s})(1.010 \text{ AU} - 0.967 \text{ AU})}{\left(1.444^\circ + 0.312^\circ + \frac{0.55^\circ / \text{hour}}{3 \text{ hours}}\right)}$$
$$v = 290 \text{ km / s}$$

# When do we expect WIND to see the stream interface?

WIND coordinates (GSE)

$X = 200 R_E = 0.009 \text{ AU}$

$Y = -52 R_E = -0.002 \text{ AU}$

$$0.005 \text{ AU} \left( \frac{1.496 \times 10^8 \text{ km}}{\text{AU}} \right) \left( \frac{290 \text{ km}}{\text{s}} \right) = 2600 \text{ s}$$

Expected time of arrival at WIND is about 45 minutes after arrival at A

# Historical Review - Pickup He<sup>+</sup>

## Interstellar Origin

### First Direct Measurements

*Möbius et al., 1985 (pickup He<sup>+</sup>)*

*Gloeckler et al., 1993 (pickup H<sup>+</sup>)*

*Geiss et al., 1994 (pickup N<sup>+</sup>, O<sup>+</sup>, Ne<sup>+</sup>)*

## Energy Spectra of Pickup Ions

### Variation of the Cutoff Energy $E_{\text{cutoff}}$

- To Zeroth Order:  $V_{\text{cutoff}} = 2 * V_{\text{sw}}$
- But: Relative Speed between neutral He and  $V_{\text{sw}}$  has to be taken into account

Möbius et al., 1999

# CIR Stream Interface - it's work in progress

## Solar wind at CIRs

- In situ signatures with STEREO HI observations
- Multi-spacecraft observations (longitudinal variations, CIR geometry)
- Rarefaction regions
- Compositional signatures at higher resolution

## Suprathermals in CIRs

- Measurement of  $\text{He}^+$  with high time resolution during CIR
- Development of suprathermal tails - directional information
